The Anti-Glitch

A [magnetar](#) is a type of highly magnetized [neutron star](#). Their extremely strong magnetic fields are produced in the fiery [supernova](#) that gave birth to the neutron star. Generally the spin periods of these objects gradually decrease with time. But sometimes these objects show a sudden increase, or "glitch", in their spin period. The cause of these rapid spin-ups is not well known, but is [believed to be due](#) to a sudden coupling between the rapidly spinning interior of the neutron star and the more slowly spinning surface. Recently, however, observations with NASA's [Swift](#) observatory have shown a phenomenon never before seen: a sudden slowdown in the spin period of a magnetar. This magnetar, called 1E 2259+586, can be seen in the [XMM-Newton](#) X-ray image above as the blue-white source embedded in a [supernova remnant](#) called CTB 109. This sudden slowdown is a puzzle to astronomers. Interestingly, a few weeks before the "anti-glitch", 1E 2259+586 produced a brief, intense X-ray burst which was observed by the [Gamma-ray Burst Monitor](#) aboard NASA's [Fermi Gamma-ray Space Telescope](#). Perhaps this outburst signalled a sudden change in the neutron star's interior, leading to the rapid spindown. Whatever happened, astronomers note that since the anti-glitch, 1E 2259+586 spin has continued to slow down at a faster rate than before.
